Clinical Policy: Inhaled Nitric Oxide

Description
Inhaled nitric oxide (iNO) is a selective pulmonary vasodilator in which its mechanism of action results in smooth muscle relaxation. Several studies have suggested that iNO improves oxygenation, particularly in trials of term and near-term neonates with hypoxic respiratory failure. iNO has been shown to reduce the need for ECMO (extracorporeal membrane oxygenation) without increasing neurodevelopmental, behavioral, or medical abnormalities at 2 years of age.

Policy/Criteria
I. It is the policy of health plans affiliated with Centene Corporation® that inhaled nitric oxide (iNO) therapy is medically necessary when meeting the following:
   A. Initiation of therapy, both of the following*:
      1. iNO will be administered via endotracheal tube or tracheostomy;
      2. One of the following indications:
         a. Hypoxic respiratory failure in newborns ≥ 34 weeks gestational age at birth with all:
            i. Evidence of pulmonary artery hypertension (PAH), one of the following:
               a) Well-documented, clear clinical evidence of pulmonary hypertension despite maximal respiratory support;
               b) Echocardiogram suggestive of PAH;
            ii. Absence of unrepaired congenital diaphragmatic hernia except when used as a bridge to surgical repair of congenital diaphragmatic hernia;
            iii. Conventional therapies such as mechanical ventilation, administration of high concentrations of oxygen (80-100%), high-frequency ventilation, induction of alkalosis, neuromuscular blockade, and/or sedation have failed or are expected to fail;
            iv. Oxygen index (OI) ≥ 25. The OI is calculated as the mean airway pressure (cm H2O) times the fraction of inspired oxygen (FiO2) times 100 divided by the partial pressure of arterial oxygen (mm Hg);
         v. Response seen with administration of up to 40 ppm trial of iNO (defined as a PaO2 increase ≥ 20 mm Hg or a 20% decrease in OI);
      b. Perioperative management in children, and infants ≥ 34 weeks gestational age at birth, both of the following:
         i. One of the following indications:
            a) Congenital heart defect and one of the following:
               1) iNO therapy for vasodilation is used in response to cardiac bypass surgery to repair a congenital heart defect that is causing PAH;
               2) Perioperative stabilization and management of hypoxia;
            b) Pulmonary hypertensive crisis associated with heart or lung surgery (including immediately pre-operatively for congenital diaphragmatic hernia);
i. Initiation of alternative vasodilator therapies during iNO administration with the intent to wean iNO* (e.g. sildenafil or others);

c. COVID-19 diagnosis**, both of the following:

   i. Severe acute respiratory distress syndrome (ARDS);

   ii. Hypoxemia despite optimized ventilation and other rescue strategies.

**Note:** If no rapid improvement in oxygenation is observed, treatment should be tapered off.

B. Continuation of iNO therapy*:

1. Member/enrollee has previously met initial approval criteria, and one of the following:

   a. Continues to require iNO as evidenced by a continued O2 requirement of 80-100%;

   b. A weaning protocol has been initiated after a 4-6 hour period of stability, indicated by O2 requirement decreased/decreasing to 60-80% or OI ≤ 10.

*Note: Extended administration of iNO beyond 48 hours requires secondary review by a medical director.

II. It is the policy of health plans affiliated with Centene Corporate that iNO is not medically necessary for any other indications such as preterm infants < 34 weeks gestation at birth, acute bronchiolitis, bronchopulmonary dysplasia (BPD), congenital diaphragmatic hernia (CDH) (except as noted above), adult respiratory distress syndrome (except as noted above) or acute lung injury, treatment in adults with positive vaso-reactivity testing, post-op cardiac surgery in adults, and vaso-occlusive crises in member/enrollees with sickle cell disease because safety and effectiveness have not been established.

Treatment Regimen

The American Academy of Pediatrics (AAP) recommends that iNO should only be administered according to a formal protocol that has been approved by the Food and Drug Administration (FDA) and the institutional review board and with informed consent.

Since no one standard protocol has been issued for iNO treatment, the following is one guideline to assist in determining appropriate initiation and continuation of treatment. The recommended starting dose of iNO for term infants is 20ppm. A positive response generally occurs in less than 30 minutes with a PaO2 increase ≥20 mmHg (or 20% decrease in OI). If there is no response, the dose may be increased up to 40 ppm. In premature infants, the initial dose used in studies was 10 ppm with an increase up to 20 ppm in non-responders. Doses of up to 80 ppm have been used, but the potential for increasing toxicity without additional benefits occurs at doses greater than 40 ppm.

Per Peliowski, weaning can occur following improvement in oxygenation and after a 4 to 6 hour period of stability, during which the inspired oxygen concentration is decreased to 60% to 80%, or the OI falls to ≤10. At 4-6 hour intervals, the dose can be decreased by 50%, as long as the OI remains ≤10. When stability is maintained at iNO dose of 5 ppm, weaning should occur by 1
**Clinical Policy**

**Inhaled Nitric Oxide**

ppm every 4 hours and discontinued at 1 ppm if oxygenation status remains with <60% oxygen with PaO₂ consistently >50 mmHg. If deterioration occurs during or after weaning occurs, the dose should be increased to the previous level or iNO restarted. Once the infant stabilizes again, weaning should occur more slowly, taking place over a 24 to 48 hour period.

In general, patients who responded to iNO therapy typically require treatment for only 3-4 days, with randomized trials demonstrating that 90% of treated infants were off iNO therapy within one week of initiation. Patients should be monitored for potential toxic effects by measuring the serum methemoglobin concentration, levels of nitrogen dioxide at the airway opening, and ambient air contamination. Decreased platelet aggregation, increased risk of bleeding (including intracranial hemorrhage), and surfactant dysfunction can also occur from iNO toxicity.

**Background**

A large and well-designed multicenter trial was conducted by the Neonatal Research Network in 235 infants with gestational age ≥34 weeks who had severe hypoxic respiratory failure (OI ≥25) and did not have congenital diaphragmatic hernia. Infants were randomly assigned to iNO or control (100% oxygen). Fewer infants in the treatment group died within 120 days or received ECMO therapy, (46% versus 64%; relative risk 0.72, 95% CI 0.57-0.91) compared to control. This difference was entirely due to decreased requirement for ECMO (39% versus 54%); there was no difference between groups in mortality.

In a systemic review by the Cochrane database, similar findings of fewer requirements for ECMO and no difference in mortality were noted. Fourteen randomized trials were found in term or near term infants with hypoxia. iNO improved oxygenation in approximately 50% of the treated infants. Within 30 to 60 minutes of beginning therapy, PaO₂ increased by a mean of 53 mmHg and OI decreased by a mean of 15.1. Outcome did not appear to be affected by whether infants had echocardiographic evidence of persistent pulmonary hypertension. No benefit was noted in those with congenital diaphragmatic hernia, indeed there is a suggestion that outcome was slightly worsened.

In preterm infants <35 weeks gestation, a systematic review by the Cochrane database found 14 randomized controlled trials of iNO. The authors concluded that iNO as a rescue therapy for the very ill ventilated preterm infant does not appear to be effective and may increase the risk of severe intraventricular hemorrhage. Later use to prevent BPD does not appear to be effective. Early routine use of iNO in mildly sick preterm infants may improve survival without BPD and decrease serious brain injury; further studies are needed to confirm these findings. Extremely preterm infants and infants with pulmonary hypoplasia may develop pulmonary hypertension. No clinical trials are available to guide prediction of response to iNO in these cohorts. A trial of iNO in preterm infants with documented pulmonary hypertension or in infants with pulmonary hypoplasia may be beneficial, however, the evidence remains inconclusive. In addition, patient selection criteria has not been defined. Additional studies are needed to identify the subset of preterm infants for whom iNO is beneficial.

Furthermore, a 2018 retrospective analysis of 993 extremely preterm infants (born at 22 to 29 weeks’ gestation) compared infants receiving iNO with propensity-matched controls, and did not find a significant association between iNO exposure and mortality.
iNO has been well-studied in patients with acute lung injury and acute respiratory distress syndrome (ALI/ARDS). While iNO may improve oxygenation temporarily, it has not been shown to improve clinically important outcomes such as duration of mechanical ventilation, 28-day mortality or one-year survival. Furthermore, iNO does not improve oxygenation in all patients and the factors that may predict a good response are still uncertain.

In an updated Cochrane database review, the evidence was insufficient to support iNO in any category of critically ill adults and children with acute respiratory distress syndrome. Although iNO results in a transient improvement in oxygenation, it does not reduce mortality and may be harmful, as it seems to increase renal impairment.22

A Cochrane Summary for the use of iNO for pulmonary hypertension (PH) following surgery in infants and children with congenital heart disease found no benefit of it to assist in recovery. In the four randomized trials reviewed, there was no difference found in mortality or other outcomes reviewed. Due to the minimal data that was available, the authors found it difficult to draw valid conclusions regarding effectiveness and safety of this treatment in the select population. In a later study, iNO was effective in reducing the risk of development of PH crisis in PAH-congenital heart defect patients after cardiac repair in a placebo-controlled study.16 Infants with PAH-congenital heart defects receiving iNO had fewer PH crises and shorter postoperative courses without concomitant side effects related to the medication.

2015 guidelines on pediatric pulmonary hypertension, issued by the American Heart Association and American Thoracic Society, make a class 1, level B recommendation for use of iNO in postoperative pulmonary hypertensive crises. The guidelines state that iNO is an established therapy for postoperative pulmonary hypertension due to its selective pulmonary vasodilator properties, rapid effect onset, and ease of administration.

Research on iNO use in adults with PH is limited to case reports and small case series, which leaves the impact of iNO on survival uncertain. It has been found to successfully stabilize a variety of acutely ill and hemodynamically compromised patients with severe PH, but the outcomes data are limited and thus cannot be considered standard of care. Acute vasodilator testing is the only well established and widely accepted use of iNO in patients with PAH. Patients with a positive vasoreactivity test are candidates for a trial of calcium channel blocker therapy.

INO has numerous potential harms that must be considered when determining the risks and benefits of treatment. These potential harms include renal dysfunction, DNA strand breakage and base alterations which are potentially mutagenic, immunosuppression that could increase the risk of nosocomial infection, and a possible increase in methemoglobin and NO2 concentrations, which must be monitored frequently. Also, iNO may produce toxic free radicals; however, it is unknown if these are more harmful than ongoing exposure to high fractions of inspired oxygen.

Due to the rapidly evolving COVID-19 pandemic, the National Institutes of Health (NIH) has developed treatment guidelines, relying heavily on experience with other diseases, supplemented with evolving personal clinical experience with COVID-19, and incorporating the rapidly
Inhaled Nitric Oxide

The guidelines will be updated frequently as published data and other authoritative information becomes available.

In adults with COVID-19 and acute hypoxemic respiratory failure, conventional oxygen therapy may be insufficient to meet the oxygen needs of the patient. Options include high-flow nasal cannula oxygen, noninvasive positive pressure ventilation, or intubation and invasive mechanical ventilation.

The recommendations for mechanically ventilated adults include the following:

- For mechanically ventilated adults with COVID-19 and ARDS, the Panel recommends using low tidal volume (Vt) ventilation (Vt 4–8 mL/kg of predicted body weight) over higher tidal volumes (Vt >8 mL/kg) (AI). (strong recommendation, one or more randomized trials with clinical outcomes and/or validated laboratory endpoints)
- For mechanically ventilated adults with COVID-19 and refractory hypoxemia despite optimized ventilation, the Panel recommends prone ventilation for 12 to 16 hours per day over no prone ventilation (moderate recommendation, one or more well-designed, nonrandomized trials or observational cohort studies).
- For mechanically ventilated adults with COVID-19, severe ARDS, and hypoxemia despite optimized ventilation and other rescue strategies, the Panel recommends a trial of inhaled pulmonary vasodilator as a rescue therapy; if no rapid improvement in oxygenation is observed, the patient should be tapered off treatment (optional recommendation, expert opinion).
- There are insufficient data to recommend either for or against the routine use of extracorporeal membrane oxygenation for patients with COVID-19 and refractory hypoxemia (moderate recommendation, expert opinion).28

Potential risks and challenges with COVID-19 patients include aerosolization and clogging of bacterial/viral filters used in ventilator circuits when pulmonary vasodilators are being administered. iNO may be preferred since it is associated with a lower need to change filters with resultant reduction in the risk to the respiratory healthcare provider.29

Coding Implications

This clinical policy references Current Procedural Terminology (CPT®). CPT® is a registered trademark of the American Medical Association. **Important Reminder**

This clinical policy has been developed by appropriately experienced and licensed health care professionals based on a review and consideration of currently available generally accepted standards of medical practice; peer-reviewed medical literature; government agency/program approval status; evidence-based guidelines and positions of leading national health professional organizations; views of physicians practicing in relevant clinical areas affected by this clinical policy; and other available clinical information. The Health Plan makes no representations and accepts no liability with respect to the content of any external information used or relied upon in developing this clinical policy. This clinical policy is consistent with standards of medical practice current at the time that this clinical policy was approved. “Health Plan” means a health plan that has adopted this clinical policy and that is operated or administered, in whole or in part, by Centene Management Company, LLC, or any of such health plan’s affiliates, as applicable.

The purpose of this clinical policy is to provide a guide to medical necessity, which is a component of the guidelines used to assist in making coverage decisions and administering
Inhaled Nitric Oxide

benefits. It does not constitute a contract or guarantee regarding payment or results. Coverage
decisions and the administration of benefits are subject to all terms, conditions, exclusions and
limitations of the coverage documents (e.g., evidence of coverage, certificate of coverage, policy,
contract of insurance, etc.), as well as to state and federal requirements and applicable Health
Plan-level administrative policies and procedures.

This clinical policy is effective as of the date determined by the Health Plan. The date of posting
may not be the effective date of this clinical policy. This clinical policy may be subject to
applicable legal and regulatory requirements relating to provider notification. If there is a
discrepancy between the effective date of this clinical policy and any applicable legal or
regulatory requirement, the requirements of law and regulation shall govern. The Health Plan
retains the right to change, amend or withdraw this clinical policy, and additional clinical
policies may be developed and adopted as needed, at any time.

This clinical policy does not constitute medical advice, medical treatment or medical care. It is
not intended to dictate to providers how to practice medicine. Providers are expected to exercise
professional medical judgment in providing the most appropriate care, and are solely responsible
for the medical advice and treatment of member/enrollees. This clinical policy is not intended to
recommend treatment for member/enrollees. Member/enrollees should consult with their treating
physician in connection with diagnosis and treatment decisions.

Providers referred to in this clinical policy are independent contractors who exercise independent
judgment and over whom the Health Plan has no control or right of control. Providers are not
agents or employees of the Health Plan.

This clinical policy is the property of the Health Plan. Unauthorized copying, use, and
distribution of this clinical policy or any information contained herein are strictly prohibited.
Providers, member/enrollees and their representatives are bound to the terms and conditions
expressed herein through the terms of their contracts. Where no such contract exists, providers,
member/enrollees and their representatives agree to be bound by such terms and conditions by
providing services to member/enrollees and/or submitting claims for payment for such services.

Note: For Medicaid member/enrollees, when state Medicaid coverage provisions conflict with
the coverage provisions in this clinical policy, state Medicaid coverage provisions take
precedence. Please refer to the state Medicaid manual for any coverage provisions pertaining to
this clinical policy.

Note: For Medicare member/enrollees, to ensure consistency with the Medicare National
Coverage Determinations (NCD) and Local Coverage Determinations (LCD), all applicable
NCDs, LCDs, and Medicare Coverage Articles should be reviewed prior to applying the criteria
set forth in this clinical policy. Refer to the CMS website at http://www.cms.gov for additional
information.
